

The design of AI Group Call for couriers

面向快递员的AI聚合外呼设计

As a one-stop intelligent service platform featuring aggregate AI Group Call, it is launched to streamline courier process and meet recipients' diverse needs, responding to the dilemma where the number of couriers fails to match the soaring number of express packages.

It provides couriers with standardized call content to go with AI Group Call, and they can call or text recipients in group through AI voice assistants. Recipients' preferences can be confirmed within 10 minutes, which would have taken 3 hours in a traditional way. It leads to a significant reduction in both communication costs and a substantial increase in service quality by minimizing negative human impact.

This platform enables couriers to fill in recipients' information only by scanning QR codes, ensuring higher work efficiency, fewer dialing errors and recipients' privacy. Also, it provides personalized and standardized services for individuals and enterprises respectively. After AI calls, recipients' diverse preferences will be sorted out, analyzed and further completed through the Big Data and AI, so that customer profiles will be developed to simplify tedious selection process for recipients.

01 Background

According to statistics, on average, each courier needs to deliver 300-500 parcels in China every day.

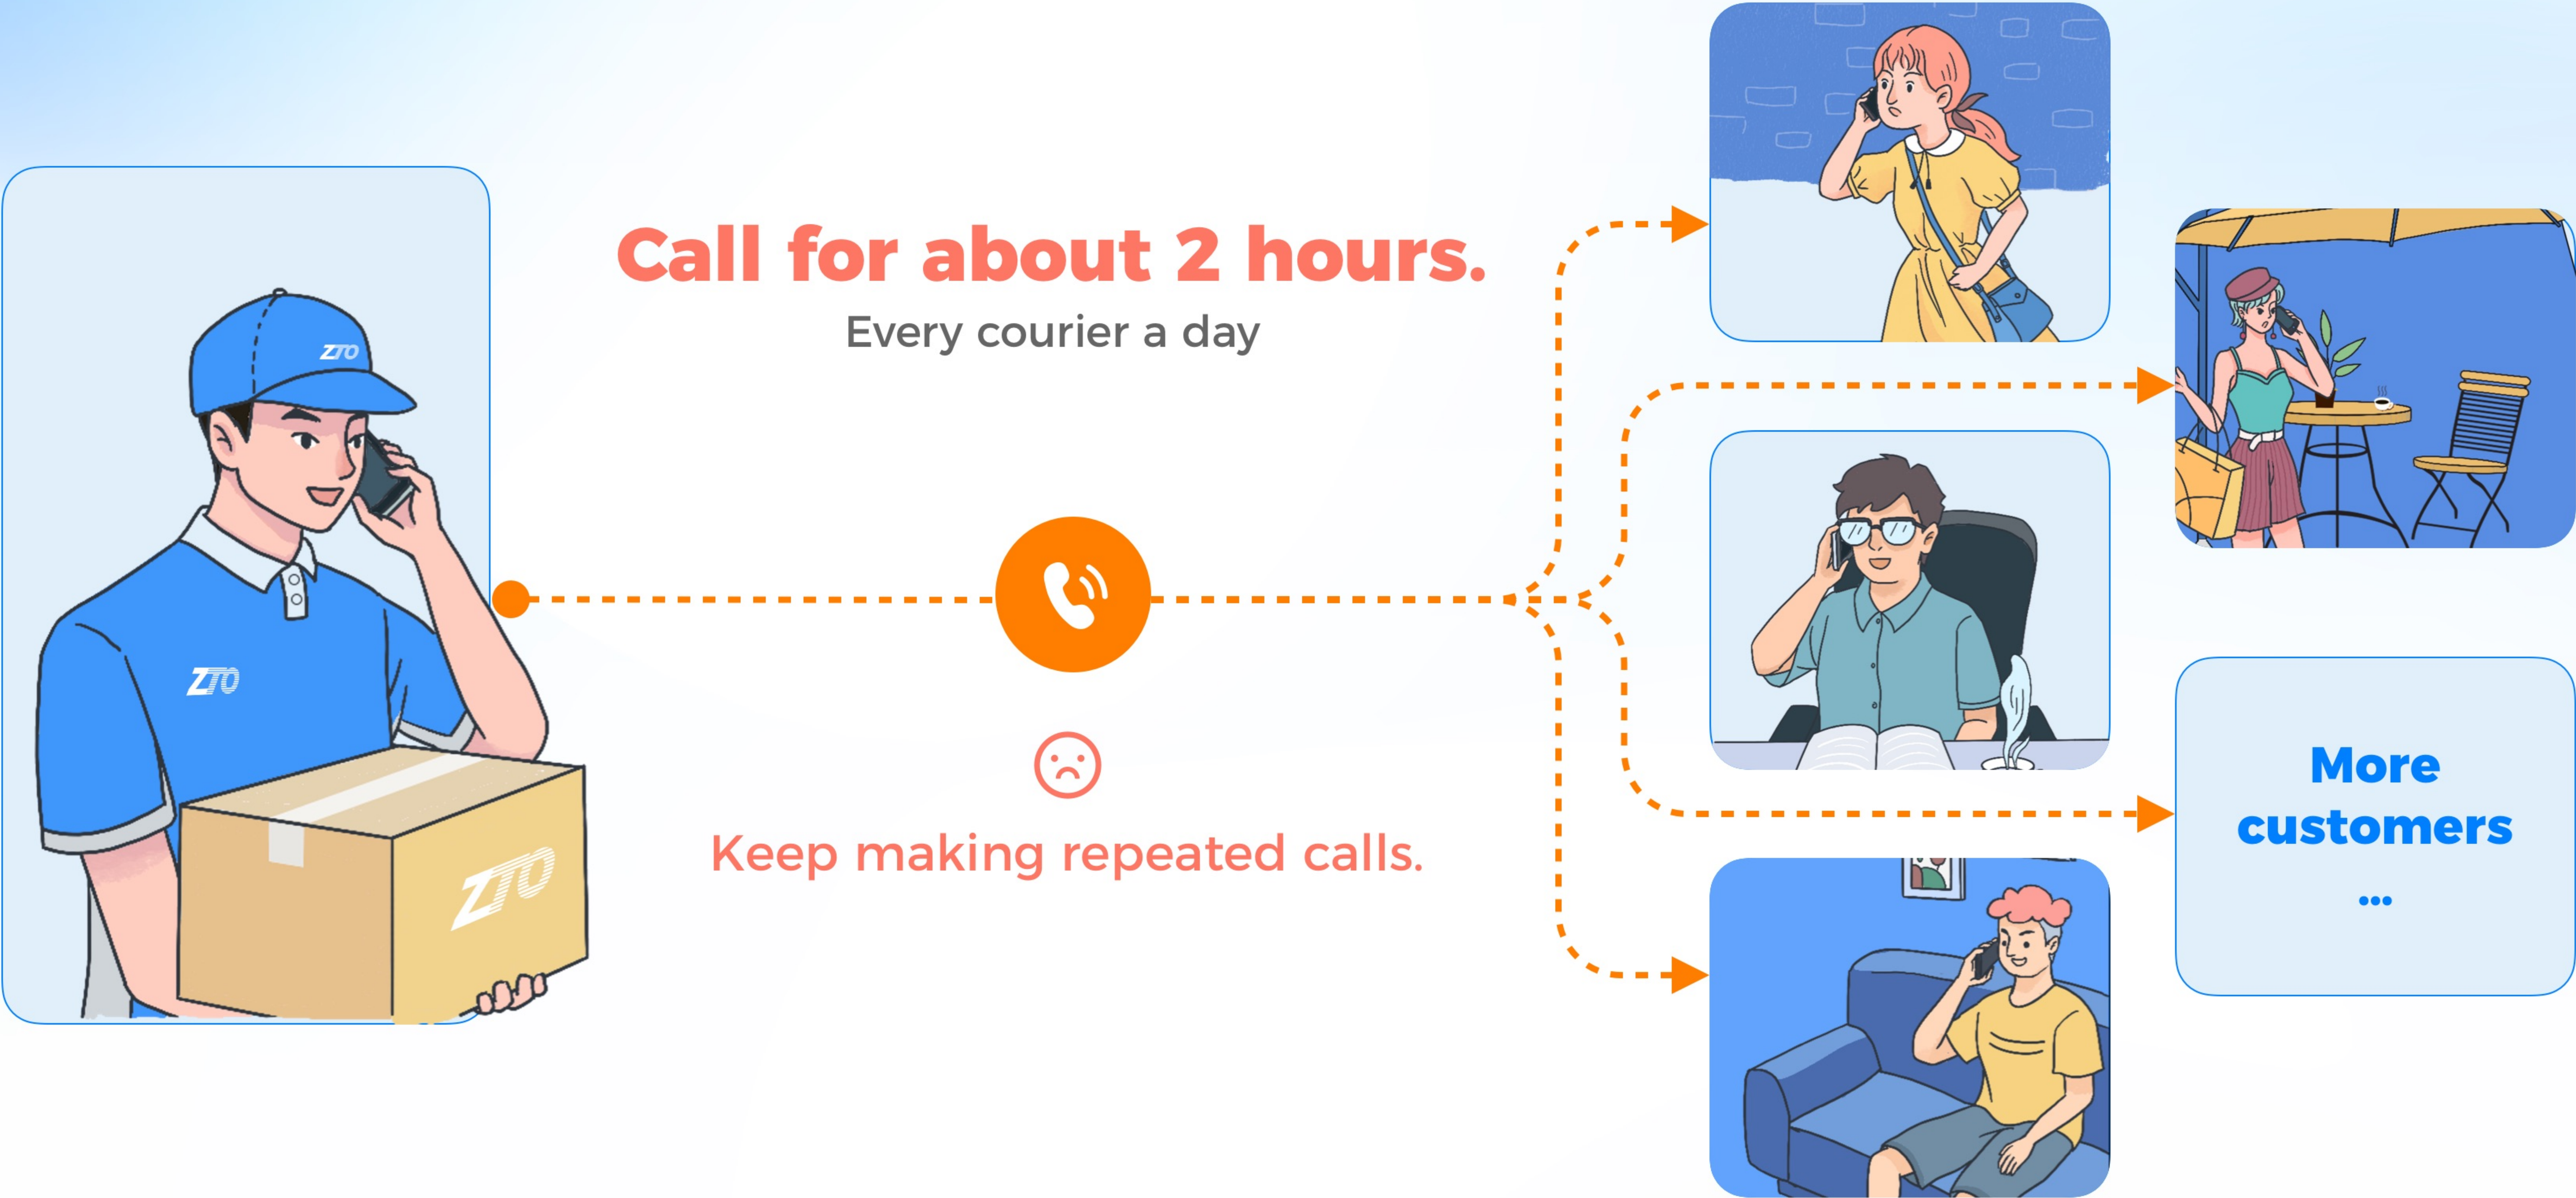

Deliver 300-500 parcels

Every courier a day

02 Pain points

The couriers inquire about the delivery requirements by calling recipients, which takes about 2-3 hours a day.

03 Design solution

Through our big data analysis, from thousands of call recordings, we found that the communication content between couriers and recipients mainly focused on three high-frequency call scenarios:

All recorded service calls are authorized by the customer.

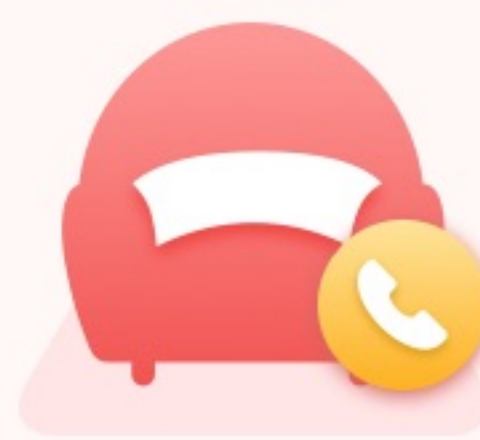

Three high-frequency call scenarios

Do you allow the package to be placed at the collection point?

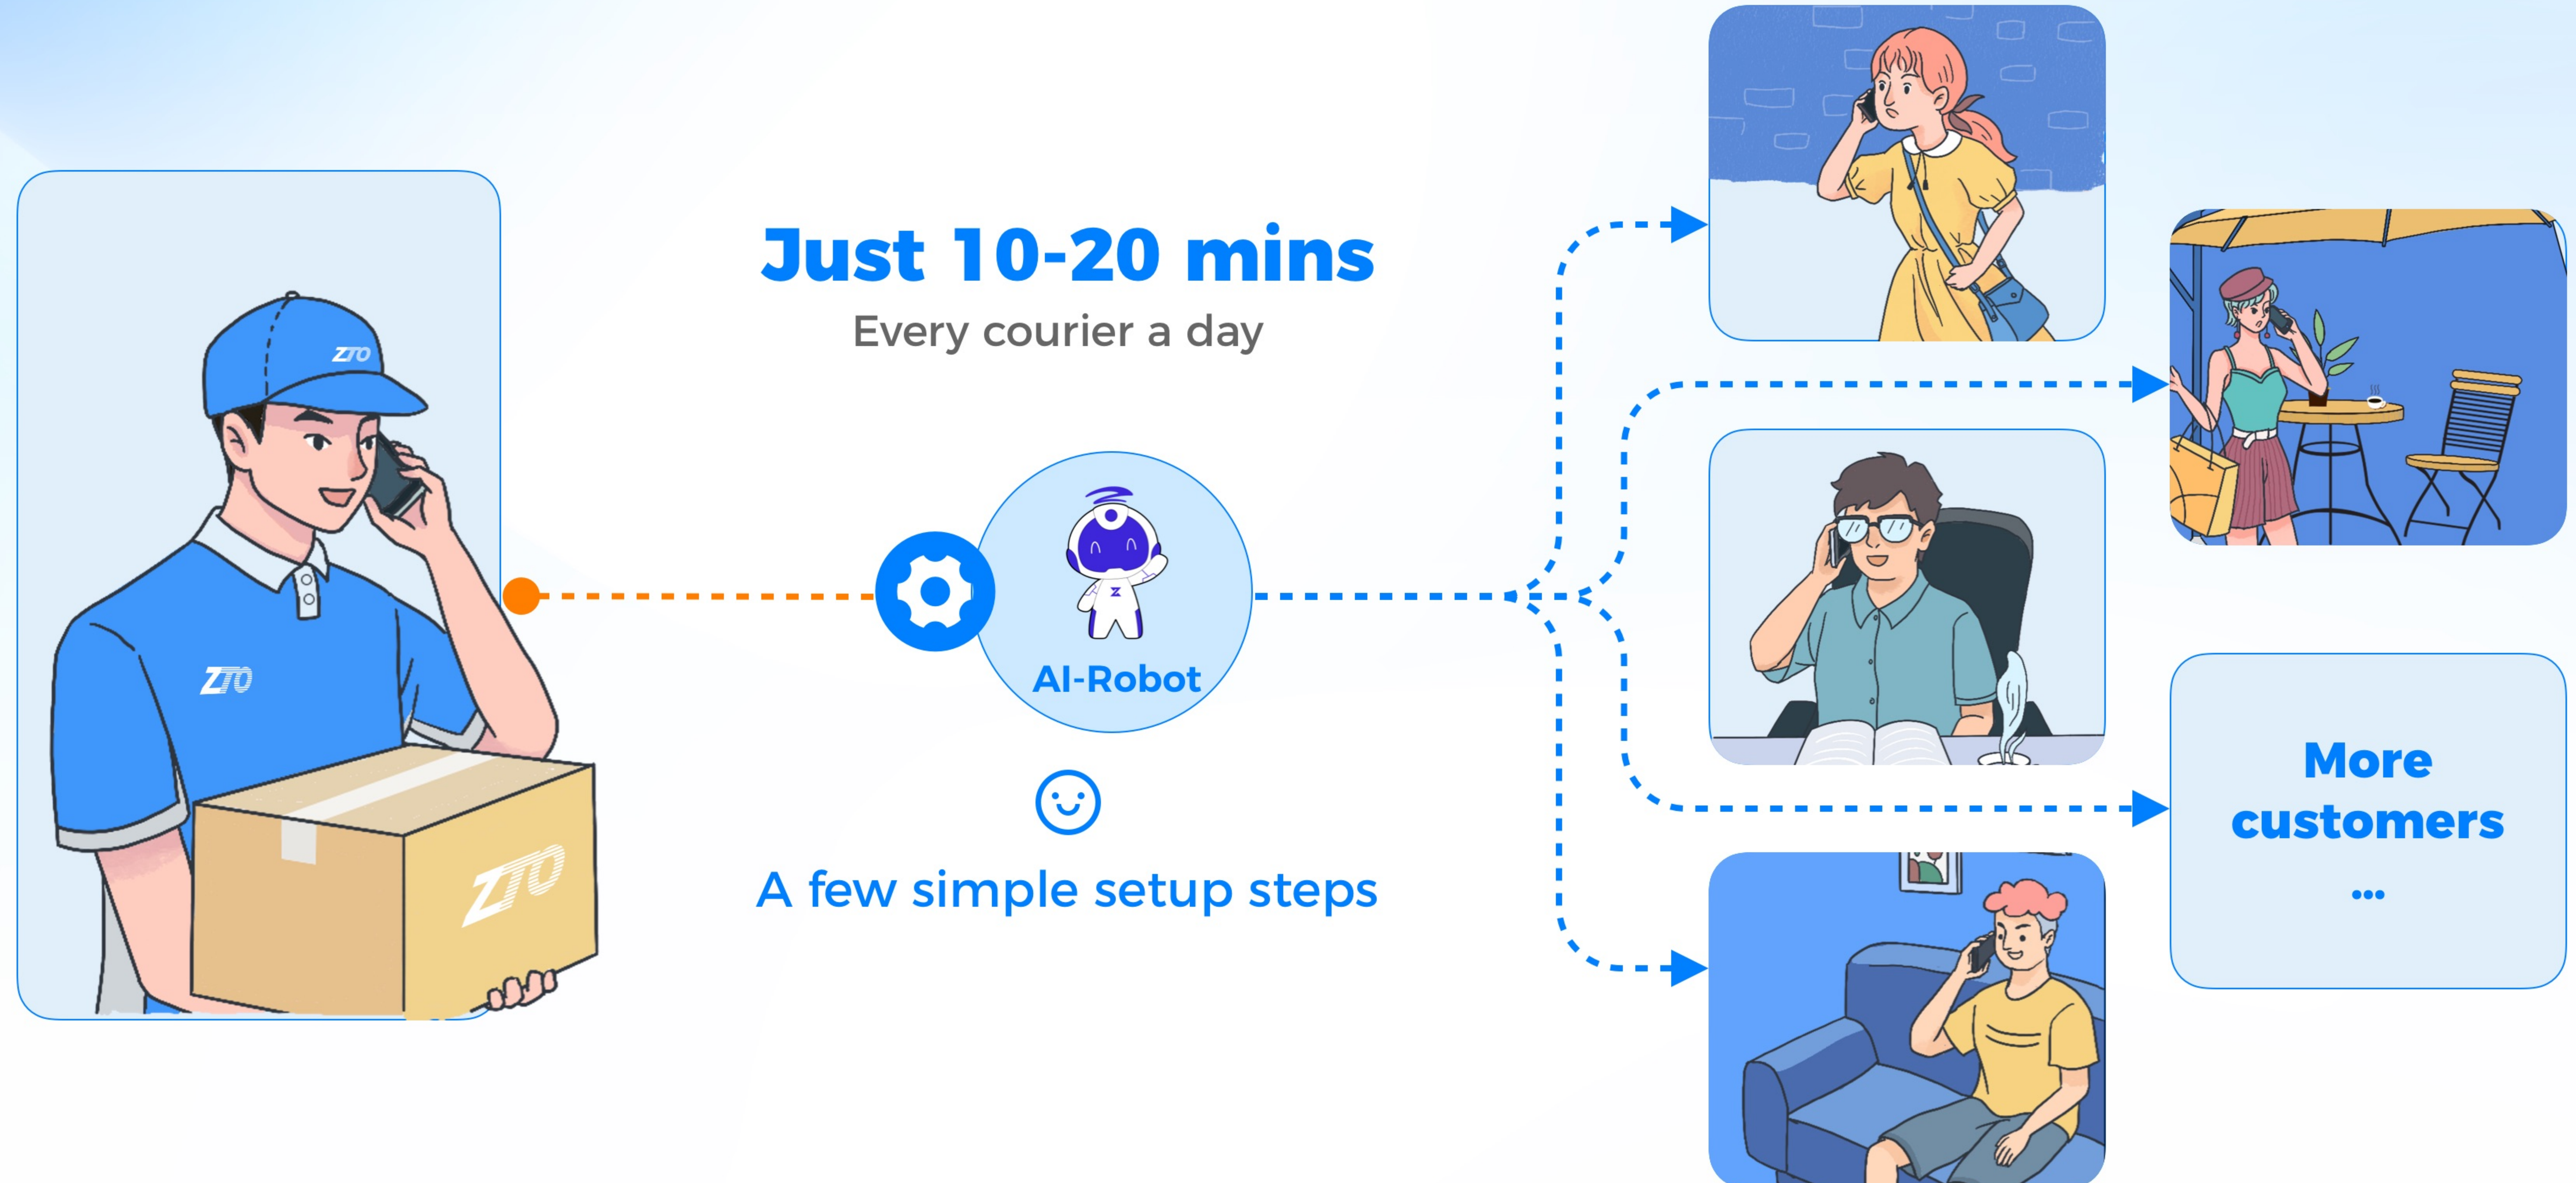

Do you need home delivery service?

Can you receive packages on holiday?

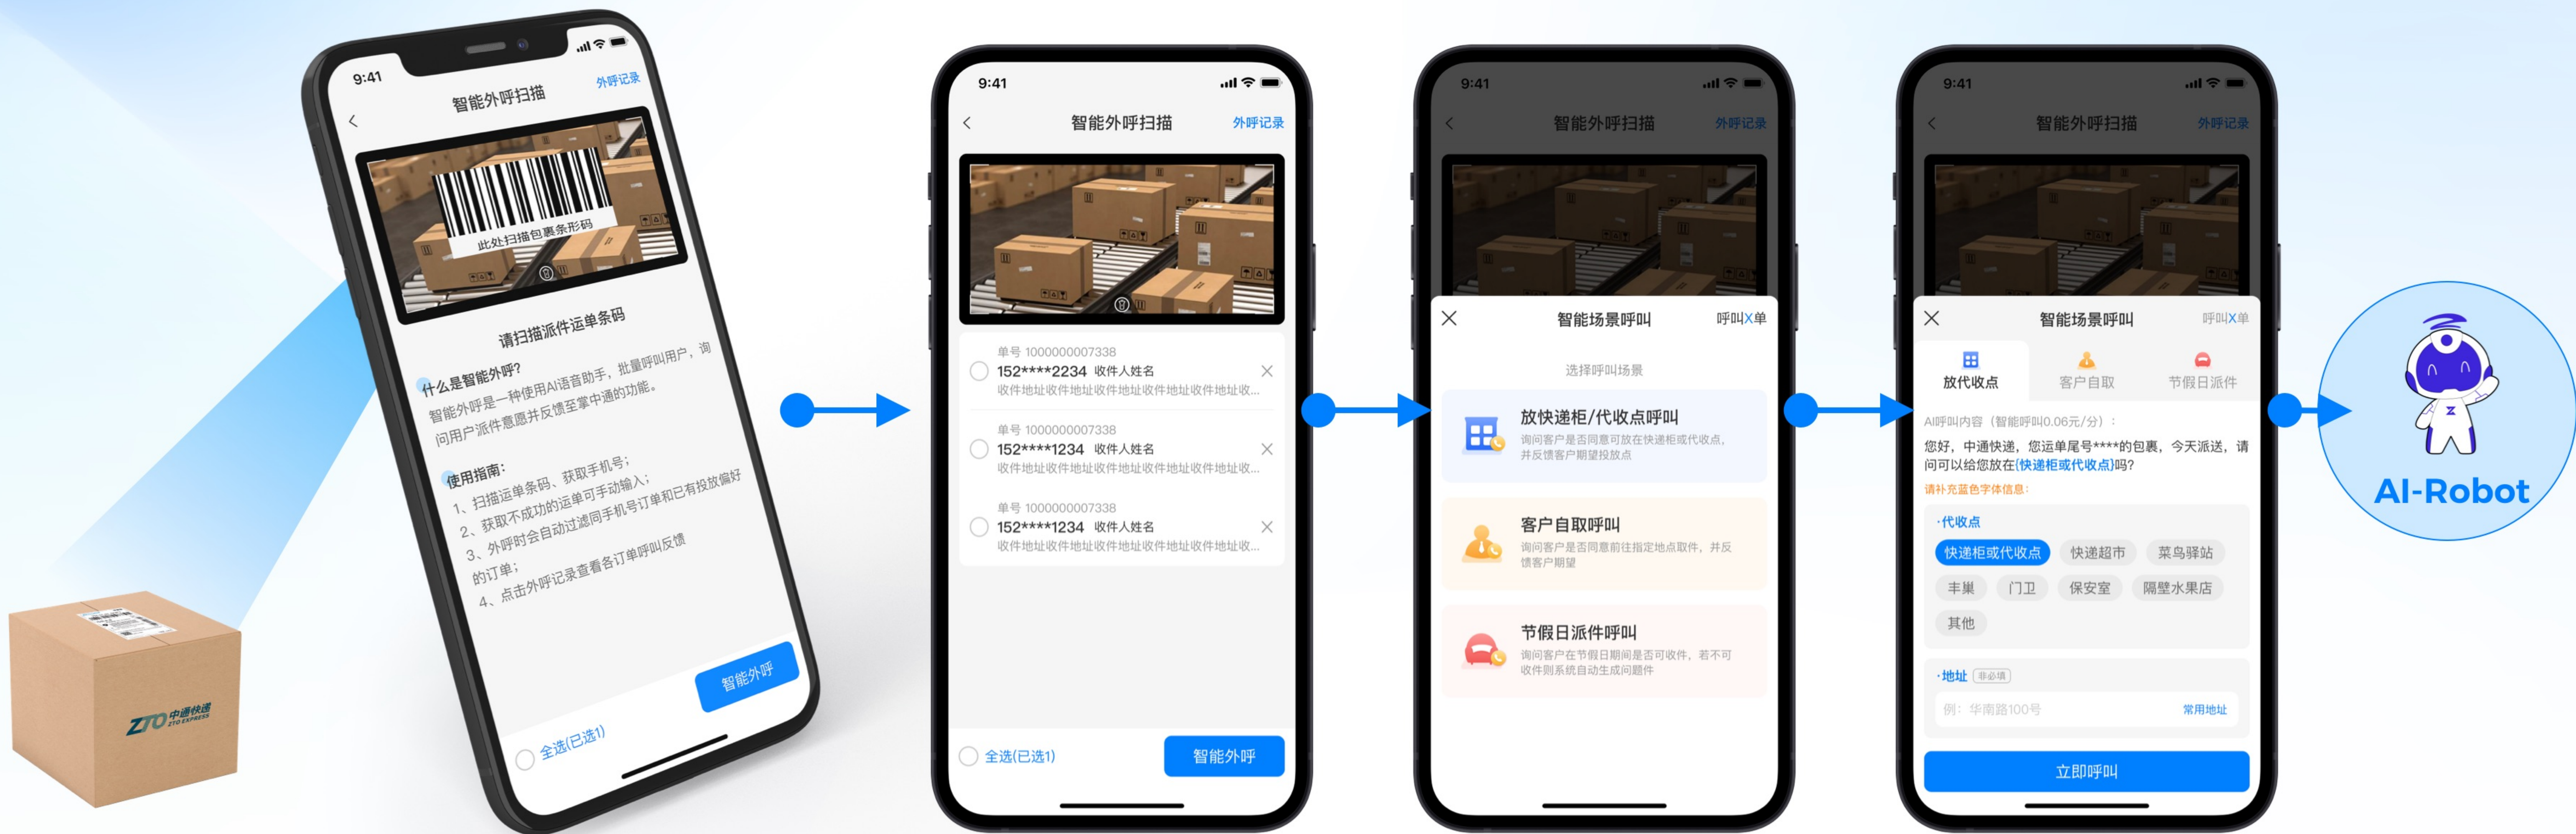

03 Design solution

We can use AI-Robot to help couriers call recipients instead of repeated manual behavior. It can communicate with up to 200 recipients at the same time through a few simple setup steps. It can collect recipients' needs, feed back to couriers and guide them to provide reasonable delivery services.

03 Design solution

The mobile phone scans the packages to get the customer's phone numbers (privacy encryption processing) that need to be called. Then the couriers select the appropriate call scenarios and set it up in detail, so that the AI-Robot can immediately call the customers and communicate with them.

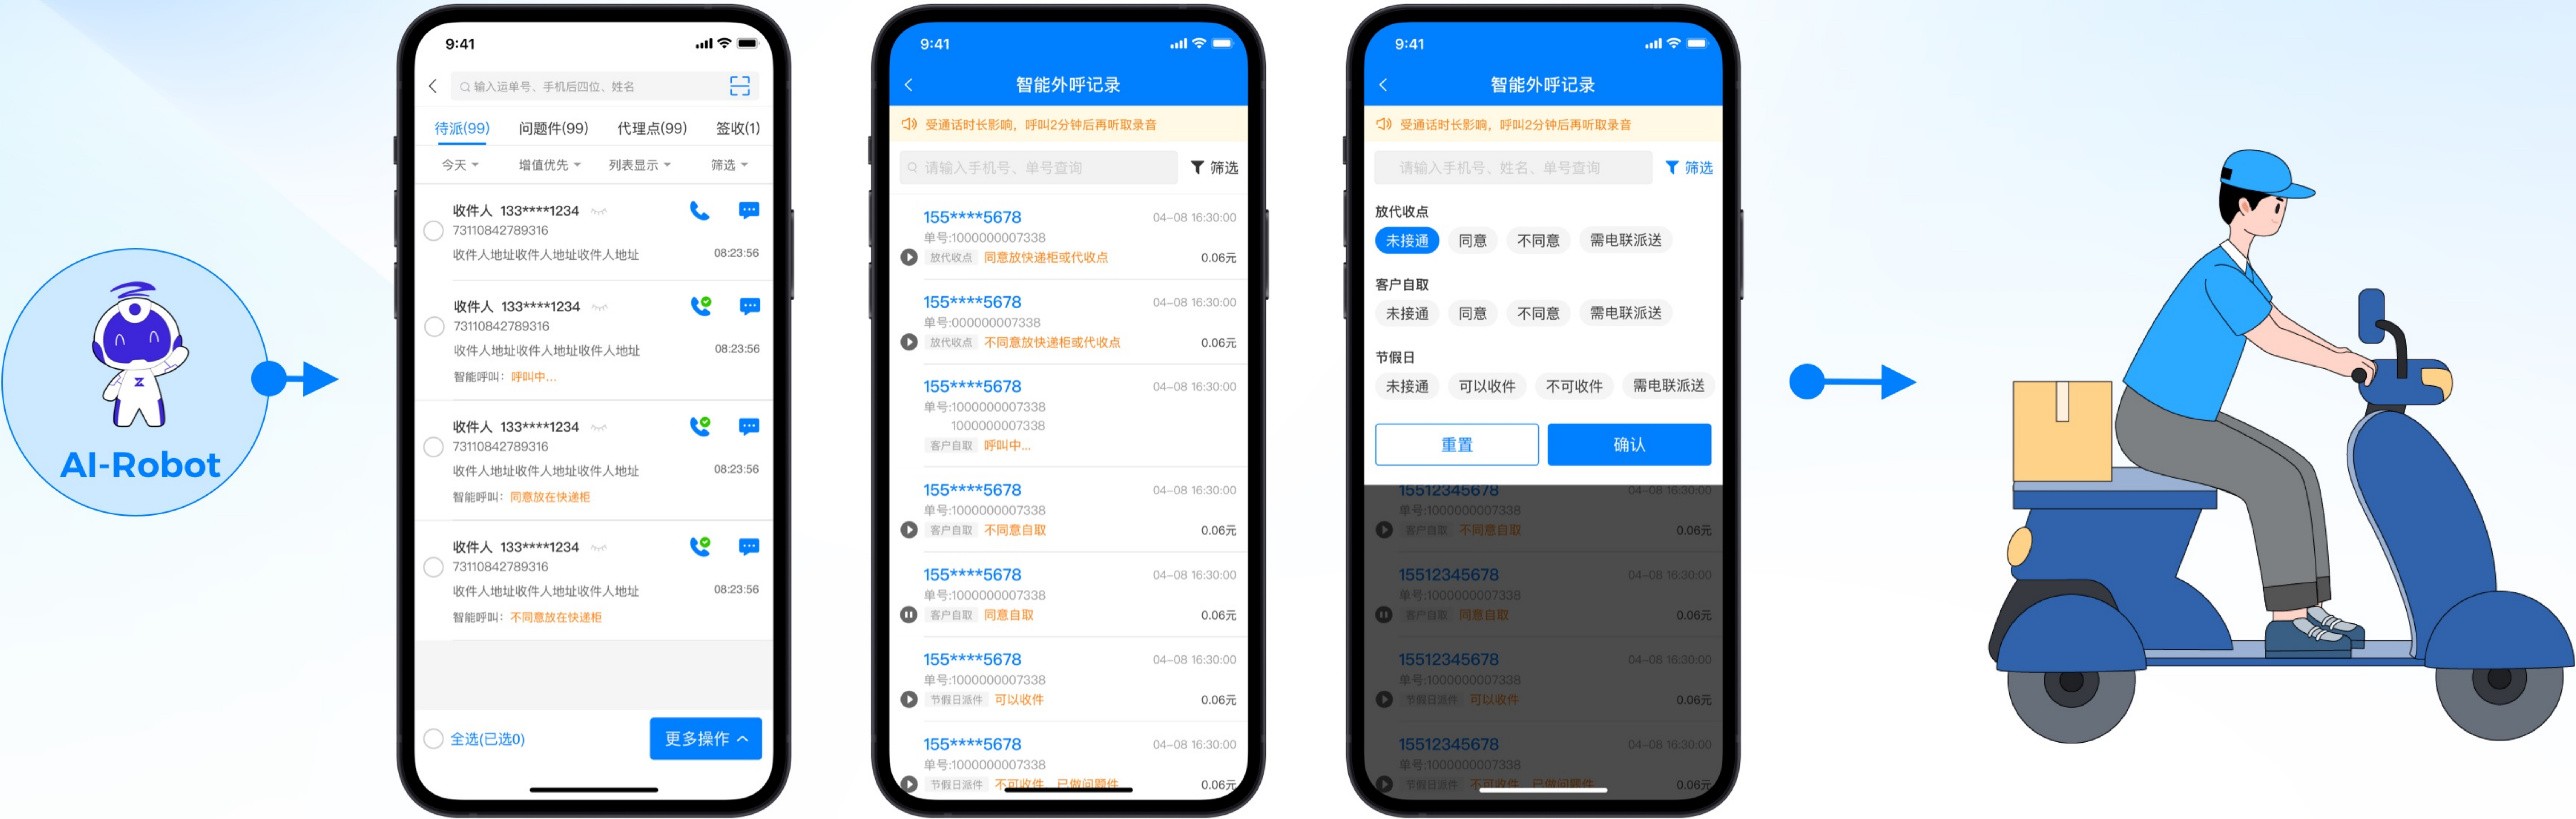

Scan the packages to get phone numbers (privacy encryption)

Select the appropriate call scenarios

Set it up in detail

03 Design solution

When the AI- Robot calling is completed, the customer's needs will fed back to the courier after the communication with recipients. Couriers can deliver reasonably according to the customer's needs.

The AI-Robot will display the requirements of the corresponding delivery task customer on the courier's mobile phone.

04 Design highlights

This design greatly improves higher couriers' work efficiency. (**from the original 2 hours to about 10 minutes**);

For recipients, we provide more **standardized service** and consistent processes to avoid the decline in service quality caused by human interference.

We can even **predict recipients' future needs and preferences** through big data, so that we can better serve customers.
